Abstract

Full-Stack Mission Application Development.

FAIRCHILD, KELLEN (Department of Math and Computer Science).

Missions is a very significant part of the life of many practicing Christians worldwide. However, like any endeavor aiming to accomplish a substantial goal, mission projects require significant personnel and logistics management, and if this capacity is lacking, projects can become remarkably difficult to manage. To help begin to remedy this problem, the Mission2Go system was designed. Using server-side JavaScript and Microsoft SQL Server, this application allows for the creation of teams, projects, and the registration of members. The program allows the user to view all projects scheduled to occur in the next 15 days and gives the option to edit project and team details, assign a different team to a project, change budget details, change team members and project dates, and other such pertinent information. By having this application hosted on a server, this app could make life drastically easier for regional coordinators, pastors, church boards, and more. When this application is complete, it will be able to create and control login sessions into the application, and facilitate more efficient administration of mission actives through registrations and team reassessments.

ACKNOWLEDGMENTS

Without the support of the Mission2Go team and Josh Williams from the Church of the Nazarene's Global Mission IT Team, this project would never have become an opportunity to learn and to serve the kingdom of God. I would also like to express my gratitude to Northwest Nazarene University's computer science, math, and theology faculty for their help in giving this project the tools necessary to move forward.

Project Overview

Managing projects, teams, supplies, and general logistics for any sort of work project is absolutely essential for efficiency, productivity, and accountability. As the Church of the Nazarene seeks to make Christ known, it must stay organized in order to ensure that teams and supplies are where they are needed, when they are needed. A web-based application allowing administrators and coordinators to keep track of their teams, projects, and funds is a substantial need for many mission partnerships and Christian denominations. This application, to be effective after implementation, would need to be fast, lightweight, and easy to use. In pursuit of growth in the global church, it is fortunate that there are a variety of methods that have appeared over the last several years which are well-suited for this type of work, making the present era a great time to develop such an application. After the project and its objectives were explained by Mr. Roger Kellogg, a Work and Witness coordinator for the Church of the Nazarene, it was decided that the application would need to be capable of registering or editing teams and users, allowing users to join teams, provide a means to register new missions projects with relevant details, and provide the capability to assign a team to a project or to change a team's registration status. These functionalities were implemented with a Microsoft SQL Server database as a back-end, and with a JavaScript runtime called Node.js with front-end-focused libraries Express.js and Pug.js to allow users to view, delete, and edit records within the database from a web browser. These technologies and their uses and purposes in the final project will be explained in greater detail when they are reached.

JavaScript Frameworks and Database Integration

JavaScript is a remarkably versatile language. While this scripting language has long been used for client-side programming, several frameworks which facilitate the writing of server-side JavaScript exist. One particularly well-known and popular example of such a framework is the open-source framework Node.js (“Node.js”). The internet is full of documentation for installing a variety of packages which can facilitate diverse tasks. Such tasks include managing browser cookies or configuring database connections with parallel threads, for example. One of the more widely-used and discussed packages for this framework is Express.js, which facilitates app development with intuitive syntax and consistent parameter names for request and response objects (“Node.js Web”). This framework is compatible with Pug.js, a templating engine that can render modified HTML (“Getting Started”). Thus, all of the basic components for the structure of this application were in place.

When dealing with significant amounts of structured data, a database is an ideal solution for working with said data. This is because databases are designed to manipulate data in an efficient manner. A database prototype, developed in Microsoft Access, was received from Roger Kellogg, the project stakeholder. Fortunately, tools exist in Microsoft’s SQL Server Management Studio (SSMS) application which can migrate data and schemata from Access to Microsoft SQL Server (Microsoft 2020). Once the schema and data were migrated, connecting to this SQL database from a Node.js application was a very straightforward process due to the MSSQL package available from NPM, the Node Package Manager (“Mssql -npm”). This package provides the ability to pass values

back and forth from the client's user interface to the database and vice versa as necessary. This means that end users can view, edit, and delete records from the database without ever being aware of the database's inner workings.

Application Security Measures

Security is an important consideration when developing applications. Without some form of security strategy, potentially sensitive data could be exposed, or the application could be misused or abused, whether purposefully or on accident. In order to make the Mission2Go application more secure, two strategies were implemented. Firstly, salts and hashes were applied to user passwords to obfuscate them within the database, making it more difficult for attackers to utilize them. Secondly, managing user sessions within the application ensures that users are logged out automatically after a given period to prevent others from gaining unauthorized access.

Salts and Hashes

When considering how and where to store sensitive information, such as user passwords, social security numbers, addresses, and other such personally identifiable information, it is universally agreed that storing such information as plain text in a database is not advisable. Storing information in this way leaves it remarkably vulnerable to interception by attackers to use for their nefarious purposes. This means that developers must apply strategies to ensure that private information is as close to secure and indecipherable as possible, while still being able to decrypt these values when needed for use. Even as encryption algorithms grow increasingly complex, (and theoretically

more computationally expensive and time-consuming to crack), modern hashing and encryption algorithms can still be deciphered, leaving information security and privacy compromised. However, the addition of a randomly generated string called a salt can make sensitive data more difficult to decode, as detailed by Robert Morris and Ken Thompson of Bell Laboratories (1978). By adding a relatively long, randomly generated string to the password before putting it through the chosen hashing algorithm, the password becomes much more complex and therefore more difficult to crack, in theory.

For this project, I chose the SHA-512 hashing algorithm due to its ease of use in Microsoft SQL with the HASHBYTES function (“Hashbytes,” 2016). I also chose this method due to learning that this is perhaps the most relevant algorithm supported natively in MSSQL, according to Microsoft’s documentation on the HASHBYTES function (“Hashbytes,” 2016). A salt for the user’s password was generated using the uniqueidentifier datatype paired with the *NewID* function, as detailed in Microsoft’s documentation on these SQL keywords (“Uniqueidentifier” , 2017). The salt is stored along with the passwords. Authentication for login to the app works by utilizing the following procedure:

- 1 Send inputted username and password securely over HTTPS to the database.
- 2 Find the username and corresponding hashed password and salt.
- 3 Append the salt to the password, and hash the result.
- 4 If the result of the hash matches the value stored in the database, login is successful.

The advantages of this system are plentiful, and while there are potentially more secure strategies, I found spending excessive time on cryptography to be beyond the scope of this project. As a result, the best reasonable effort was made to ensure security in good faith. Additionally, it is likely this application will have relatively few users, at least initially, and attackers likely would not be able to find very much actionable intelligence anyway.

User Sessions

The Node.js and Express.js frameworks have robust and secure session-managing middleware which uses encrypted cookies and a randomly-generated session ID to ensure users have permission to perform certain actions. In addition, if a user is forced to leave their workspace or forgets to log out, the session can be set to close on its own and log the user out after a set period of inactivity to prevent unauthorized persons from gaining access to sensitive information. Various packages are available for Node.js which allow the storage and access of sessions. Notably, keeping track of sessions with a file store system or in the database is not an ideal solution. Database and file accesses take time, and could slow down the application drastically, especially with multiple simultaneous users. Fortunately, there is an effectively perfect solution to this problem. This solution consists of two major parts. Firstly, the Linux Mint operating system was used with the MATE desktop environment (Linux Mint Institute, 2020). Secondly, a memory-based session store that is exclusive to Linux platforms, called Redis, was installed and implemented (Redis Labs, 2020). These pieces of software helped to circumvent the problem of the database bottleneck.

Once the system was migrated to its new operating system, the user session management solution could be implemented with Redis (Redis Labs, 2020). While there is a native memory cache for user sessions in Node.js, the authors of the package make it abundantly clear that it is prone to memory leaks and is suitable only for testing, not for production (“Express-session”). Redis states that companies such as StackOverflow and Twitter use their user session solution, and this suggests that it has a reputation for security and reliability (“Who’s Using Redis?”). Redis is, for all intents and purposes, an open-source database or data structure that is based entirely in memory, which has several advantages over conventional database and file session storage (“Redis”). A Linux terminal running a Redis instance can be seen in Figure 1. The documentation for Redis lists some of its advantages, including speed and volatility settings (Redis’s storage options are highly configurable), and optimization of memory usage for speed and efficiency (“Session Management”). Due to these advantages and recommendations from the overwhelming majority of sources I consulted on this matter, Redis was by far the best choice, even though it created a delay in development due to migration difficulties.

Figure 1. Terminal Running Redis

Project Planning

The Mission2Go Project was born when Mr. Roger Kellogg visited an Intro to Senior Project class at Northwest Nazarene University in early 2020. Shortly afterward, a team was assembled, the members met to discuss the basic requirements and goals for the project, and a system architecture was provided by freelance software developer Mr. Jorge Vasquez. Vasquez's project stack is diagrammed in Figure 2.

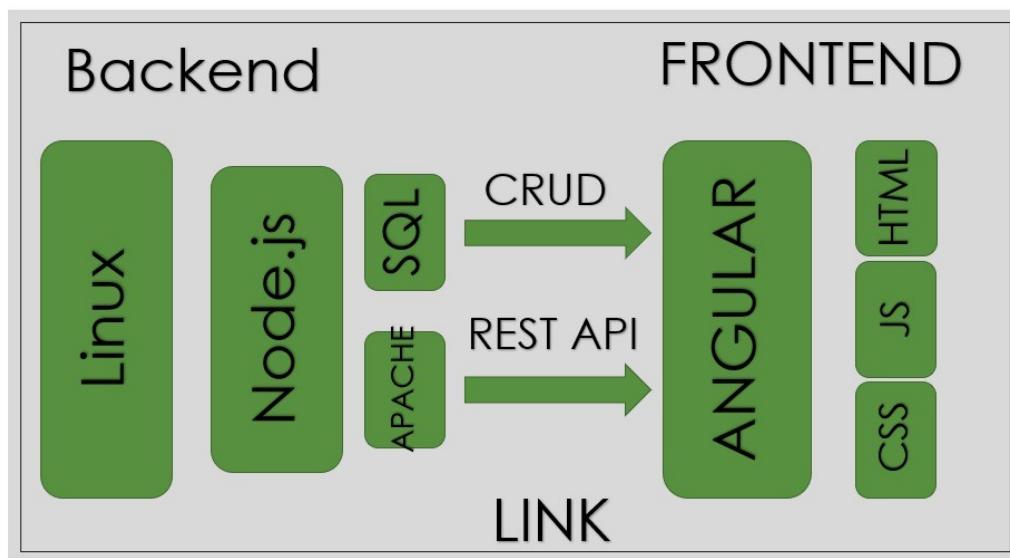

Figure 2. Project Stack (J. Vasquez, personal communication, 2020)

This portion of the project is focused on the server and database components. However, cascading style sheets written by Ms. Telah Dickerson, a senior computer science student at Northwest Nazarene University, will be implemented to improve the look of the front-end in the near future. Due to its high flexibility, speed, popularity, wealth of

documentation, and open-source nature, Node.js was chosen immediately as the back-end scripting language. While MySQL was initially chosen, due to the team's greater familiarity with Microsoft SQL, MSSQL was later chosen instead. PhpMyAdmin was used early on in the development process, but was later rejected due to issues with database migration and inflexibility with navigation and other such functions within the final application. The speed and flexibility of page and form design with the Pug.js templating engine and Node.js made it immediately apparent that this combination of technologies was by far the principal option. While discussing the project's agenda, the following requirements for the application were established:

- 1 Allow a person to join a team
- 2 Assign a team to a project
- 3 View (and edit, if necessary) flight information
- 4 View and edit project funds
- 5 Create a secure method of logging into the application

Once these requirements were selected and the application stack was decided, development could proceed.

Development

This project began with significant amounts of research. With a remarkable amount of choices of libraries to choose from, research needed to be conducted to find the most scalable and expandable libraries and frameworks on which to build the application's basic logic and frame. Express.js was chosen for this due to the ease with which routing

and common web features, such as GET and POST requests, could be implemented. This package could also be easily implemented with Node.js' standard HTTP and HTTPS packages, which can be used to host a server on a specified port number. After this server was operational, a login system to access the application needed to be created and implemented on the server. This system was implemented as a SQL stored procedure, which allows the execution of procedural database operations. This procedure was written in SSMS, as described in the “Salts and Hashes” subsection of the “Application Security Measures” section. If a user is successfully authenticated, they are directed to the home page of the application.

After this basic login functionality was shown to work reliably, the home page was developed. This homepage was based on a form from the Access prototype. Many of the queries necessary for these forms were accessible from within Access' design view, but some modifications were needed due to slight syntax differences. The Pug.js templating engine has a functionality which allows the use of a *forEach loop*, which iterates over an array until the end of its data is reached, and thus facilitating the printing of SQL result sets by utilizing an array of objects. The items in this array can then be printed as data in HTML objects, which for the majority of this project were exclusively tables. By printing buttons at the end of each table row, the user can choose to edit a given record. A variety of buttons and links were also included on this page to allow logging out, signing up a user for a team, editing records, and other such actions. However, much of this functionality required substantial changes to the database's structure and stored procedures.

Database Schema

Referential integrity and the enforcement of foreign keys are very important concepts in designing a database that retains accuracy and usability. When the Access prototype's schema was migrated to Microsoft SQL, many of these foreign key constraints and references were not maintained. This is due to the existence of a different method of reference creation in Access, in which primary and foreign keys can be different data types, such as tinyint and int. As a result, the table structures needed to be fixed throughout much of the database. Additionally, it is common practice when developing with Node.js to use stored procedures, rather than using query strings to manipulate data, as this is known to improve security and performance. As a result, stored procedures were written in order to implement the updating, insertion, and deletion of records, and to ensure such operations cascaded when necessary to avoid records pointing to nonexistent data. Microsoft's SQL Server Management Studio has several tools which allow easy visualization of table and column dependencies, as well as making the creation or deletion of such dependencies very straightforward (Microsoft, 2020). Figure 3 shows an image of the main area of the schema of the Mission2Go database within one such tool, the Database Diagrams utility.

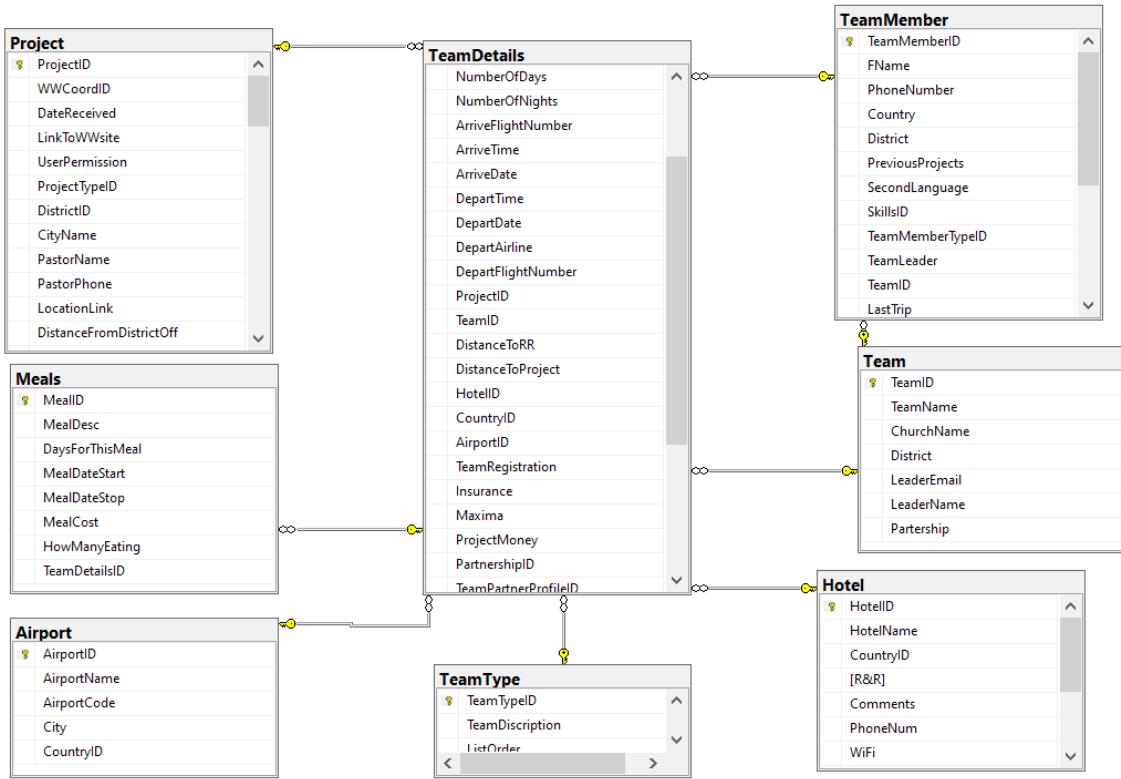

Figure 3. Database Schema

By utilizing such tools, the database could be structured to be fast, accurate, and ensure changes in one table would be reflected in tables which depended on these tables. Figure 3 details how the “TeamDetails” table is related to other tables. The table acts as a bridge table between the “Project” table and the “Team” table, and has relations to other tables that add additional information about a project/team assignment, such as the hotel the team is staying in or what airports will be used for arrival and departure.

While the tools SSMS provides were very helpful, there were still difficulties that arose while attempting to finalize the database’s structure. For example, the bit data type

is used in SQL as the equivalent of a Boolean variable in most other programming languages. However, updating the bit data type presented some problems, notably that deciding to cancel a team did not update the team's record properly. Additionally, in SSMS, values cannot update from the NULL state unless this state is explicitly handled. As a result, novel ways of circumventing these troublesome issues needed to be found. For the first issue, the bit type values were changed to integers, but still only set to the values 0 or 1. For the second, all null values were updated to have a value of 0, or for strings the value 'NONE PROVIDED'. These changes allowed updates, inserts, and deletions work as they needed to in order for the application to function properly. However, upon testing this structure and stored procedures in the database, the task remained of implementing them to cooperate with the client side of the application.

User Interface (UI) Creation via Pug.js

Perhaps one of the most significant reasons Node.js is well suited for this particular project is its extensive support of various database languages. Node's Microsoft SQL (MSSQL) package allows the execution of stored procedures, as well as the printing of SQL error messages directly to the application's console. This capability also makes debugging and tracing the movement of data significantly easier than this would be otherwise. This is due to the fact that the package can print all SQL resultsets and recordsets in their raw form to the console, making monitoring data incredibly straightforward and intuitive. However, Node.js also provided some difficulties during the development of this application. Most notably, some documentation for certain packages was outdated, requiring me to email its authors or issue a GitHub error report or

pull request. Additionally, due to the existence of several extensions for connecting to SQL Server, some packages used objects known as connection pools, whereas others used a global connection variable for all SQL actions and requests, making referencing documentation an almost daily occurrence. However, over time, these issues became less prominent. With the available database packages, stored procedure results could easily be accessed in an array and have their values assigned to corresponding variables in an array of objects. Figure 4 demonstrates how this can be done.

```

app.get('/ScheduledTeamsView&Edit', function (req, res){

    var UsNm = req.session.user;
    console.log(req.sessionID);
    if(UsNm == null && sessionID == null){res.redirect('/');}
    console.log(`logged in as: ${UsNm}`);
    const promise2 = new Promise(function (resolve, reject) {
        var check2 = new sql.Request();
        var tableArray = [];

        check2.execute('ProjectTeamTables').then(function(result){
            var len = result.recordset.length;
            var today = new Date();
            for(var i = 0; i < len; i++) {
                tableArray.push({
                    "Maxima": result.recordset[i].Maxima,
                    "TeamName": result.recordset[i].TeamName,
                    "CountryName": result.recordset[i].CountryName,
                    "Days": Math.round((result.recordset[i].ArrivalDate - today)/(1000*60*60*24)),
                    "ArrivalDate": moment(result.recordset[i].ArrivalDate).format('YYYY-MM-DD'),
                    "DepartDate": moment(result.recordset[i].DepartDate).format('YYYY-MM-DD'),
                    "NumTeamMemb": result.recordset[i].NumTeamMemb,
                    "ProjectID": result.recordset[i].ProjectID,
                    "FName": result.recordset[i].FName,
                    "ProjectMoney": result.recordset[i].ProjectMoney,
                    "SumOfUSD": result.recordset[i].SumOfUSD,
                });
            }
            //The above loop creates an array of objects...
            //...which is easily rendered on the client side upon redirect and rendering
            resolve(tableArray);
            //console.log("redirect success");
            res.render('ScheduledTeamsView&Edit', {tableArray : tableArray});
            delete tableArray;
        });
    });
});
```

```
});  
});  
});
```

Figure 4. Example Array Creation

In Figure 4, results from the “ProjectTeamTables” procedure are loaded into the array “tableArray” and each item in the object is given a label. On the second to last line, the page showing this data is rendered, and this new object is passed with it, allowing the page to display the results of the query as the data changes over time. In a similar fashion, data that is inputted by the client into a form can be pulled with POST requests, and passed to the SQL object before running the procedure and returning results. The resulting client view is shown in Figure 5.

Figure 5. Application Home Screen

Once a procedure was established for communicating between the client and server-side components of the application, the creation of the basic necessary forms was a remarkably straightforward process, though with some exceptions. These forms will later be improved with cascading style sheets (CSS) written by Ms. Tela Dickerson. An example of a data entry form can be seen in Figure 6.

The screenshot shows a Google Chrome window with the title "Project Teams Record Editor - Google Chrome". The address bar indicates the page is "localhost:5000/createT...". The main content area is titled "Edit Records [AUTHORIZED USERS ONLY]" and displays the message "Currently Creating a New Team:". Below this, there are five input fields labeled "New Team Name:", "New Church Name:", "New District:", "New Leader Email:", and "New Leader Name:". After the "New Leader Name:" field, there is a dropdown menu labeled "New Partnership:" with options "YES" and "NO". The "YES" option is currently selected. At the bottom of the form is a "Save Changes" button.

Figure 6. Example Data Entry Form

Some forms created difficulties due to the project stack's inability to pass more than one object (e.g. an array) to a given page prior to rendering. Because of this limitation, values needed to be held while all necessary variables were printed or gathered on separate forms before finally operating on the database with these variables as parameters. While this was initially difficult to plan, it became progressively easier as these situations continued to arise throughout the application's development.

The layout of the user interface for the Mission2Go application was initially very simple, containing only the necessary buttons and text fields for essential functioning, with little to no regard to user experience, intuitiveness, or aesthetics. These forms were created with the Pug.js templating engine, which has syntax practically identical to HTML, with the exception of some interpolation features and the complete absence of closing tags, although these tags can be included to suit the user's preference ("Tags"). Values are entered into forms, and forms are rendered with current data for users, via the use of GET and POST requests, respectively. An example of the use of these requests is shown in figures 7 and 8.

```

<!DOCTYPE html>
<html lang="en">
  <head>
    <title>Registration</title>
    <meta charset="utf-8"/>
    style
    include ./CSS/registration.css
  </head>
  <body>
    <nav>
      <a href="/">Log In</a>
    </nav>

    <div>

      <h1> Mission 2 Go Registration</h1>

      <form action="register" method="POST">
        <label for="newUser">New User Username: </label>
        <input id="newUser" type="text" name="newUser" required><br><br>

        <label for="newPass">New User Password: </label>
        <input id="newPass" type="text" name="newPass" required><br><br>

        <label for="newEmail">New User Email: </label>
        <input id="newEmail" type="text" name="newEmail" required><br><br>

        <input type="Submit" value="Register">
      </form>
    </div>
  </body>
</html>

```

Figure 7. Client Side View

Figure 7 shows the Pug.js code for a simple form that takes inputs for a username, password, and email address. This code creates an HTML form with an action called “register” and implements the POST method. Figure 8 shows the handling of this form once submitted.

```

app.get('/registration', function(req,res){
    res.render('registration');

});

app.post('/register', function(req, res){
    var newUser = req.body.newUser;
    var newPass = req.body.newPass;
    var newEmail = req.body.newEmail;
    const promiseReg = new Promise(function (resolve, reject) { //promise awaits results before proceeding
        var R = new sql.Request();
        R.input('newUser', sql.NVarChar(64), newUser); //pass user and pass to stored procedure
        R.input('newPass', sql.NVarChar(64), newPass);
        R.input('newEmail', sql.NVarChar(64), newEmail);
        R.execute('registerUser').then(function (result, recordset){
            var flag = result.returnValue;
            resolve(flag);
        }).catch(function(error){
            console.log(error);
            sql.close();
            reject(error);
        });
    });
    promiseReg.then((verdict) => {
        if (verdict === 0) {
            res.send("THIS USER ALREADY EXISTS");
            res.redirect('/login');
        }
        else{
            //console.log("...ACCOUNT CREATION SUCCESSFUL...");
            res.redirect('/');
        }
    });
});
});

```

Figure 8. View Handler- Back End

Figure 8 shows the server-side handling of the form in figure 7. The “app.get” block at the top uses a GET request to render the view to the client. Once the “Submit” button is clicked to submit the form, the “app.post” block is called. This block pulls data from the form using calls to the request (req) object and specific variables from the client side code in figure 7, such as the “newUser” variable. After this is complete, these values are passed to a SQL stored procedure to store them in the appropriate table, and a value is returned from this procedure specifying if registration was successful or if an account already exists. In this manner, GET and POST requests are used to move data from the client to the server where it is to be processed and stored.

Conclusion

While this project certainly was difficult and had a remarkably steep learning curve, it was incredibly rewarding and challenging. Perhaps the best way to learn software development skills is to work on projects in skills that are foreign in order to learn and become proficient, if not a master in these skills. With the rapid advancement of computing technologies, this need to take on new challenges is a mainstay in the field of computer science. This project exposed its creators to database design and server-side programming, and while I have performed both of these tasks for courses throughout my time at NNU, this project certainly increased my appreciation and enjoyment of these aspects of system design.

Although the Mission2Go application does still have some minor bugs, the basic functionality works sufficiently to be used in the field. Bugs will be fixed as quickly as

possible and as they appear during use to ensure the most stable and effective application possible. Teams can be assigned to projects with ease, and new records can be created. Many of the bugs in the application are due to difficulties with moving parameters between functions. This is because the web framework used is designed to only take two parameters, making it impossible to pass additional information effectively between functions. However, this application works relatively well and accomplishes its objectives overall.

This project serves as a lesson to its creators that just because the rules of a framework cannot seem to be broken, does not mean they cannot be bent to work toward a desired end. The project forced the team to think about problems and necessary algorithms in new ways in order to work with the strengths and weaknesses of a given technology, or to know when to switch methods or languages if necessary, to find a more advantageous methodology of approaching a solution. While this project still needs more development work, user feedback, and testing, this project could have a substantial impact on the administration of missions projects, which could certainly increase opportunities to serve for people everywhere, including the people of Northwest Nazarene University.

Future Work

While the work completed on the Mission2Go project is certainly a significant step towards streamlining the administration of mission projects and outreach all over the world, there is significant potential for this project to be improved with a more diverse

selection of operations, and perhaps the addition of new tables to the database to reflect other data that are of use and interest to a missions coordinator. Additionally, this application will certainly be able to improve in terms of its speed and efficiency, particularly for clients, as new and faster Node.js packages are developed to meet new needs, or old needs in new ways. Because the process of systems analysis and design is an iterative process, it is the team's hope that work on this application can continue into the future, perhaps as another NNU student's senior project.
